4th Semester

Computer Engg.

Subject: Object Oriented Prog Programming
Using Java

Ans-1

i) Method:

Methods in Java are used to define as behaviour or properties of any object defined in a class. It is basically a block of code that does some task.

Syntax of Method -

```
returnType methodName() {  
    // body of method  
}
```

ii) Constructor overloading :-

There is said to be constructor overloading when there are more than one constructors in a Java program, that are of same name and different parameters. We can only distinguish between two constructors when calling by their parameters.

iii) Properties of an Interface are:-

- There are only abstract methods in an interface.
- By using interface, multiple inheritance can be used.
- It has static and final keywords in it only.
- It has static and final variables.
- The 'interface' keyword is used to declare interface.
- Abstract class can't be implemented using interface.

iv)

Abstract Class

- Abstract class can have both abstract and non-abstract methods.
- There is no multiple inheritance in it.
- It can implement interface.
- It has static, final, non-static, non-final variables.

Interface

- Interface can have only abstract method.
- It can have multiple inheritance.
- It cannot implement abstract class.
- It has only static and final keywords.

vi)

throw keywordthrows keyword

- | | |
|---|---|
| <ul style="list-style-type: none"> • throw keyword is used for one exception only. • It is used with method. • In syntax, throw keyword is followed by instance variable. • It is used to throw an exception. | <ul style="list-style-type: none"> • throws keyword is used for one or more exceptions. • It is used with method signature. • In syntax, throws keyword is followed by exception's class names. • It is used to throw one or more exceptions. |
|---|---|

Section : BAns-2POLYMORPHISM :

It is the property of a substance to take different forms. 'Poly' means many and 'morphism' means ~~one~~ having forms/shapes. Polymorphism means having many forms, shapes.

for Example :

⇒ TYPES OF POLYMORPHISM :

i) Compile Time Polymorphism -
is determined In this type, the method to be involved... during the compile time of program. It involves the concept of method overloading.

ii) Run Time Polymorphism -
In this type, the method to be invoked, during the run time of program, is determined. The Run Time polymorphism involves the concept concept of method overriding.
